Road traffic accidents involving elderly people: an integrative review

Abstract

Objective: To identify the epidemiological and socio-demographic profile of elderly victims of traffic accidents reported in articles published in scientific literature from 2013 to 2018. Method: The Literatura Latino Americana em Ciências da Saúde (Latin American Literature in Health Sciences), Base de Dados de Enfermagem (Database in Nursing), Scientific Electronic Library Online, and Medical Literature Analysis and Retrieval System Online databases were used, with the guiding question being: What is the scientific production on traffic accidents involving elderly people? A total of 355 articles were found. After the application of the selection criteria, 16 were evaluated, and nine remained for final analysis. Results: The age range was 60 to 69 years and the majority of the sample were men, who were married and had low schooling. Being run over was the most frequent accident. The width of the traffic lanes and the time of the accident influenced the frequency and risk of accidents and the severity of the injuries. Conclusion: Younger elderly persons were the most affected, and being run over was the most frequent type of accident.

INTRODUCTION

Traffic accidents are one of the main causes of death in the young and adult population. This cause is also significant among the elderly, especially with the increasing size of the older population.\textsuperscript{1-4}

A study on external causes carried out by the SEADE Foundation in the state of São Paulo, Brazil, found that car accidents and falls are among the main causes of death among the elderly. When the other causes of death among this population are compared, external causes have a lower impact, but are greater within the group itself.\textsuperscript{5}

Although external causes affect the younger population more frequently, the risks of dying from accidents or violence increase dramatically among those over 60. This is caused both by the condition of exposure to risk due to locomotion and other tasks that are part of activities of daily living, as well as by the inherent difficulties of age.

Among the accidents that can affect the elderly population are Road Traffic Accidents (RTA). The number of existing vehicles is a preponderant factor for the occurrence of these accidents, involving both automobiles and motorcycles, as they cause complications in the traffic in general, and increase the risks of this type of accident.\textsuperscript{5,6} With the changing age of the population,\textsuperscript{4,6} RTA suffered by the elderly have become a major public health problem, and one with an increasing trend.\textsuperscript{7}

People in the 60 years or older age group have a higher mortality from external causes in Brazil, as well as hospitalizations from these causes within the Unified Health System (or SUS), with rates of 109 and 650 per 100,000 inhabitants, respectively, in 2008. Between 2008 and 2010, there were 413,139 hospitalizations for external causes among the elderly in the SUS, costing approximately R$570 million. These hospitalizations were mainly due to falls (62.4%), traffic accidents (8.1%) and unclassified external causes (7%).\textsuperscript{8}

Between 2000 and 2010, the mortality rate from RTA increased from 18 to 22.5 deaths per 100,000 inhabitants in Brazil. Such accidents were also the second most frequent cause of hospitalizations in the SUS between 2002 and 2011, resulting in costs estimated at R$50 billion.\textsuperscript{9-11}

Although older people are living longer and more healthily, they face new challenges, among which are traumas resulting from RTA, which significantly affect this group.\textsuperscript{10}

It was therefore felt that there was a need to better understand how RTA affect this population through the identification of published works on the subject in scientific literature, and from this knowledge provide a foundation to contribute to the preparation of preventive public policies to benefit this age group.

Therefore, the present study aimed to identify the epidemiological and sociodemographic profile of elderly victims of RTA through articles published in scientific literature from 2013 to 2018.

METHOD

An integrative review of literature was carried out, which consists of the creation of an evidence-based scientific framework. This form of knowledge production requires a methodological rigor and is effective for the analysis and critique of literature, constituting one of the main research modalities in the context of health.\textsuperscript{12}

As a research strategy, the electronic databases Medical Literature Analysis and Retrieval System Online (PubMed), Latin American & Caribbean Health Sciences Literature (LILACS), the Scientific Electronic Library Online (SciELO) virtual library and the ScienceDirect platform were used.

The inclusion criteria were: (a) articles indexed by descriptors registered in the Medical Subject Headings (MeSH) database: “Traffic Accidents”, “Elderly”, “Old Age”, “Old Adults” and in the Health Sciences Descriptors (DeCS): “Traffic Accidents” and “Elderly”; (b) articles published from 2013 to 2018 involving people over 60 years of age and (c) articles that answered the research question. The exclusion criterion was published literature other
than primary articles, excluding, in this manner, case studies, monographs, master’s dissertations, doctoral theses, chapters of books and systematic reviews.

The survey was conducted between February and April 2018, with data collection performed at two different moments. The first was the selection of articles for a complete reading, the description of which is detailed in figure 1. Initially, 936 articles were established from the chosen descriptors. A total of 848 were discarded as they did not meet the inclusion criteria (n=840) or were duplicates (n=8), leaving 90 articles potentially eligible for the study.

From a careful reading of the titles and abstracts, 65 articles were excluded because they were outside the defined age group (n=49) or did not relate to the studied subject (n=16) and, thus, 25 articles were chosen as they responded closely to the guiding research question proposed.

For the second part of the data collection, an instrument was created by the research team that contained the following items: article title, year of publication, country of affiliation of the main author, type of study and main results. Data analysis was performed in a descriptive manner, based on the Thematic-Categorical Content Analysis. This process was divided into three stages, namely: pre-analysis, exploration of material or coding and treatment of results - inference and interpretation.

### Database | Title of article | Author | Year of publication | Country of origin | Main results
--- | --- | --- | --- | --- | ---
PubMed | Street crossing behavior in younger and older pedestrians: an eye- and head-tracking study | Zito GA, Cazzoli D, Scheffler L, JägerM, Müri RM, Mosimann UP, et al. | 2015 | Switzerland | Elderly persons performed significantly worse on the visual acuity test. Older participants significantly overestimated their walking speed, but they needed more time to complete the crossing. Older pedestrians have more difficulty analyzing the movement of an approaching car when it is still far away, increasing risky decisions and decreasing performance at the intersection.

ScienceDirect | Crossing a two-way street: comparison of young and old pedestrians | Dommes A, Cavallo V, Dubuisson JB, Tournier I, Vienne E | 2014 | USA | Reduced functional skills increase the risk of collision. The elderly presented flaws when required to increase the speed and the length of their steps in comparison with younger people. The elderly also had difficulty processing information from the visual scene, as well as not looking directly at traffic, in addition to making more risky decisions compared to young participants.

PubMed | Comorbidities and Crash Involvement among Younger and Older Drivers | Papa M, Boccardi V, Prestano R, Angellotti E, Desiderio M, Marano L, et al. | 2014 | Italy | The burden of comorbidity is a self-limiting factor among elderly drivers, since the increase in comorbidities is associated with a reduction in involvement in collisions. Thus, the burden of comorbidities is a predictor of involvement in traffic accidents, regardless of gender.

PubMed | Association Between Vision Impairment and Driving Exposure in Older Adults Aged 70 Years and Over: A Population-Based Examination | Sandlin D, McGwin Jr G, Owsley C | 2014 | USA | Reduced visual processing speed was the strongest risk factor for the involvement of older drivers in vehicle collisions. Self-regulation was a highly adaptive strategy for reducing exposure to this risk.

### DISCUSSION

Globally, trauma cases are the fifth highest cause of mortality among the elderly, with cases of Road Traffic Accidents (RTA) contributing to this increase. In Brazil, the RTA-related death rate among elderly individuals has been increasing since 1996, especially in the northeast region of the country.

The demographic profile identified in several studies reveals that younger elderly persons, especially in the 60-69 age group, are the main victims of traffic accidents. However, health care costs are higher for the population of drivers aged over 65 years, as they are more likely to suffer more severe traumatic injuries and have a lower recovery capacity for these injuries than younger elderly persons, thus leading to longer hospitalization and higher costs.

When the results were analyzed by gender, men were the most affected, which may be related to their greater movement around the urban perimeter of cities, due to their greater involvement in leisure activities and as participants in the labor market.
In addition, there is a greater proportion of RTA among married elderly persons, as well as those with lower schooling, as this is one of the determinants for a greater occurrence of traumatic lesions\textsuperscript{21,29}.

Risk factors that increase the vulnerability of the elderly population to traffic accidents may be related to the aging process itself, the prevalence of comorbidities, alcohol use, polypharmacy, traffic dynamics and the structural difficulties of places the elderly attend\textsuperscript{21,22,27,37}.

When comparing risk factors between genders, employability is found to be the greatest factor for males, with arthritis the most frequent comorbidity among females, and depressive symptoms evident factors for both genders\textsuperscript{29}. Being overweight and elderly people over 65 with university degrees were other risk factors cited\textsuperscript{23}.

Another important risk factor was the use of alcohol and other drugs. One study that characterized such use in elderly drivers involved in fatal automobile collisions in the USA found that among drivers considered drug-positive, there was a 43\% greater tendency to be without a seat belt at the time of the collision. The most commonly reported drugs were antidepressants and narcotics, as well as benzodiazepines, many of which can alter driving ability if not prescribed and administered properly\textsuperscript{23}.

Literature shows that elderly pedestrians are the most vulnerable to traffic accidents. This may be explained, in addition to the functional conditions of the elderly, by current traffic conditions and improper driving behaviors, such as carelessness on the part of car drivers and motorcycle riders, as well as situations where the elderly cross the road away from crossings or when the red light is showing for pedestrians\textsuperscript{15,21,38}. Such situations potentiate trauma events in traffic and reaffirm their status as a public health problem\textsuperscript{25}.

The predominance of being knocked down among traffic accidents involving the elderly is partly related to the difficulty these pedestrians have when crossing the road, as cognitive decline is accentuated by increases in age. A study also showed the unsafe behavior of elderly people when crossing two-way streets, where they have difficulties in increasing step speed and length in comparison with young people\textsuperscript{32}. A greater risk was also perceived among elderly drivers when decelerating vehicles due to reduced sensitivity and confidence\textsuperscript{18}.

A study in Switzerland compared the behavior of young and old people at the intersection of a lane, and found that the latter looked more towards the ground than to both sides of the street before crossing than the former\textsuperscript{31}. This was justified by the fact that the elderly do not generally take a second look for potential hazards at intersections\textsuperscript{24}.

Regarding the day of the week, time of occurrence and speed of collision, when compared to traffic accidents involving younger people, accidents involving elderly people were more frequent during the day, from Tuesday to Friday, and involved a lower collision speed\textsuperscript{36}.

The most commonly reported injury patterns were traumatic brain injuries (TBI), due to the impact of parts of the vehicle or throwing the victim onto the road, and limb fractures due to the reduction in the bone mineral content characteristic of aging\textsuperscript{22,27,38}. In addition, it was also identified that in the elderly, most of the deaths at the scene of the accident were due to thoracic and pelvic injuries, while in hospitals the majority of deaths were due to abdominal injuries\textsuperscript{33}. Although these lesions may be conveniently treated, some elderly cyclists died because rescue teams did not identify early retroperitoneal bleeding after pelvic fractures, which require the careful clinical evaluation by the team that provides first response care to the injured elderly person\textsuperscript{17}.

In contrast, comorbidities help to reduce the risk of the elderly being victims of a RTA event, as they employ self-regulating behaviors. These behaviors are characterized by the self-reported decision to adopt protective strategies in traffic when perceiving their weakened physical condition, such as reducing their exposure to traffic, driving a vehicle at lower speeds and avoiding driving at night, which becomes preventive behavior\textsuperscript{14,20,31,34,36}.

With regard to the impacts of traffic accidents on the elderly population, it is known that this type of event can negatively affect the functional capacity
of such individuals, depending on the severity of the trauma. Immobilizations were the most frequent results, and the greater the intensity of the trauma, the more serious the consequences and the behavior adopted\textsuperscript{26}. It was evidenced that the elderly are more predisposed to suffering fractures or trauma to the cranial and vertebral column\textsuperscript{38}.

One initiative worthy of note involved the development of a mentoring program for elderly drivers on driving difficulties associated with aging, encouraging self-care\textsuperscript{26}. From this perspective, health services that care for the elderly, irrespective of the level of complexity, must be prepared to meet the specifics of trauma among this public, investing in professional training, infrastructure, health education, self-care practice and family participation\textsuperscript{24}. These and other initiatives can serve as incentives to prevent the growth of the morbidity and mortality of elderly people due to traffic accidents and should be stimulated in the various contexts of care of this population.

The limitations of the present study concern the heterogeneity of the studies included in the review in terms of the discussion of the results, which may have hampered a more consistent analysis. The descriptors selected may not have found all the published studies. In addition, many of the articles surveyed are restricted access, which can be considered as a limiting factor. It is important that more studies are carried out in the area of gerontology and geriatrics involving traffic accidents.

**CONCLUSION**

According to this review, the profile of the elderly persons suffering traffic accidents was: elderly persons in the age group of 60 to 69 years, males, married, with low schooling and who worked. Pedestrians were the most vulnerable, with a predominance of being knocked down. The accidents occurred most often during the day, and cranio-encephalic trauma was the most frequent injury.

In view of the results, it can be inferred that there is a need to invest in the area of urgent and emergency care, in the planning of actions that contribute to the preparation of health teams for the integral care for the elderly, noting their particular characteristics, related to the frailty of age, such as the pathophysiological alterations that can compromise the quality of life of these individuals.

A fresh approach should be taken among professionals who work directly with traffic in cities with an elderly population, with the aim of training such individuals and raising their awareness about the treatment of the elderly, avoiding greater harm.

It is hoped that other researchers are encouraged to carry out further studies in the areas of geriatrics and gerontology involving Road Traffic Accidents (RTA) in order to create strategies where this population can have more freedom in their mobility without the risk of accidents, and with a better quality of life.
